

Cox's Work

Cox did work on the difference equation, $aY_{x+1} + bY_x = q(x)$ where a and b are complex numbers that do not equal 0 and whose sums do not equal zero. $q(x)$ is a given polynomial. We will look at the more specific form, $aY_{x+1} + bY_x = (a + b)x^v$. Cox used methods similar to N.E. Norland's methods with studying the equations $Y_{x+1} - Y_x = vx^v$ and $Y_{x+1} + Y_x = 2x^v$. Cox shows that what is called the generalized Euler polynomial is a solution to $aY_{x+1} + bY_x = (a + b)x^v$.

Cox uses certain sequences of numbers. One of these sequences, $\{ k \}$ is defined by $a(k + a + b)^v + b^v k^v = 0$ where $v = 1, 2, 3, \dots, c$. In the binomial expansion k^v is replaced by k_v . So when $v=1$ we get

$$\begin{aligned} a(k + a + b) + bk &= 0 \\ ak + a^2 + ab + bk &= 0 \\ k(a + b) &= -a^2 - ab \\ k &= -a(a+b)/(a+b) \\ k &= -a \end{aligned}$$

This implies that $k_1 = -a$

We run into a little bit of a problem when $v=0$ we get

$$\begin{aligned} a(k+a+b)^0 + bk^0 &= 0 \\ a + b &= 0 \end{aligned}$$

This leaves us with no k to solve for. Cox fixes this problem by defining $k_0 = 1$. So we receive the sequence $k_0 = 1, k_1 = -a, k_2 = a(a - b), k_3 = -a(a^2 - 4ab + b^2), \dots$

Now put $k(a + b) = S$ into $a(k + a + b)^v + bk^v = 0$ and after expansion replace S^f with S_r .

So $S_r = k_r / (a+b)^v$. $a(k + a + b)^v + bk^v = 0$ becomes

$$\begin{aligned} a((a + b)S + (a + b))^v + b((a + b)S)^v &= 0 \\ a((a + b)(S+1))^v + b((a + b)S)^v &= 0 \\ a(a + b)^v(S+1)^v + b(a + b)^v S^v &= 0 \\ a(S+1)^v + b(S^v) &= 0 \end{aligned}$$

Letting $q(z)$ be and polynomial in z we have the symbolic relation

$$a^*q(S+1) + b^*q(S) = (a + b)q(0).$$

Now replace $q(z)$ by $q(z + x)$ to get $a^*q(x + S + a) + b^*q(x + S) = (a + b)q(x)$.

The symbolic expansion of $q(x + s)$ is a solution to the difference equation

$$aY_{x+1} + bY_x = (a + b)q(x).$$
