

# Bringing the Appalcart to the Tropical Setting

Amanda Copeland, Sergei Miles, Sierra Milosh, Lauren Murray

Appalachian State University

S-STEM Presentation, 2016

# Outline

- 1 Introduction
  - Assumptions
  - Basic Operations
  - Train Diagram
- 2 Optimization
  - Why Max-Plus?
  - Eigenvalue
  - Eigenvector
- 3 AppalCart
  - Teal Route
  - POP 105 Route
- 4 Conclusion
  - Future Work

## Goals

Make the most efficient model for the train system with standard departure times, and apply this system to the AppalCart routes.

## Assumptions

- Travel times of the train are constant
- Trains should wait for each other
- Trains leave as soon as possible

# Basic Operations

## Operations

- $A \oplus B = \text{Max}(A, B)$
- $2 \oplus 5 = \text{Max}(2, 5) = 5$
- $A \otimes B = A + B$
- $2 \otimes 5 = 2 + 5 = 7$

## Identities

- $\epsilon = -\infty$
- $e = 0$
- $\epsilon$ : direct path between stations does not exist
- $e$ : travel time between stations is 0

# Train Diagram

$$A = \begin{bmatrix} 2 & 5 & \epsilon \\ \epsilon & 3 & 3 \\ e & \epsilon & \epsilon \end{bmatrix}$$

$A_{ij}$  = the time from station  $j$  to  $i$

## Why Max-Plus?

- $\otimes$ : gives the arrival times of trains
- $\oplus$ : makes all the trains wait on one another

## Relating to Train Diagram

- Outer cycles
- Need for passengers

# Eigenvalue

- $|Y|_w$  = circuit weight or total travel time
- $|Y|_l$  = circuit length or the number of paths
- $\mu = \frac{|Y|_w}{|Y|_l}$
- $\lambda = \text{Max}(\mu_1, \mu_2, \dots)$
- In the train diagram  $\lambda = 3$

## Eigenvector

- Gives departure times for trains

- $A_\lambda = \begin{bmatrix} -1 & 2 & \epsilon \\ \epsilon & 0 & 0 \\ 3 & \epsilon & \epsilon \end{bmatrix}$

- To find eigenvector use  $\bigoplus_{k \geq 0} A_\lambda^k$

- $\begin{bmatrix} 2 \\ 0 \\ -1 \end{bmatrix}$

- Train 3 leaves first, a minute later Train 2 leaves, two minutes after that Train 1 leaves

# Teal Route

## Computations

- $$A = \begin{bmatrix} -1 & 2 & \epsilon \\ \epsilon & 0 & 0 \\ 3 & \epsilon & \epsilon \end{bmatrix}$$

## Results

- Teal Route is optimized for two buses
- Route could be made more efficient with 3 buses

# POP 105 Route

## Computations

- $A_\lambda = \begin{bmatrix} -1 & 2 & \epsilon \\ \epsilon & 0 & 0 \\ 3 & \epsilon & \epsilon \end{bmatrix}$

## Results

- Optimized for Friday and Saturday Schedule
- Could be more efficient Monday thru Thursday

## Future Work

- We started to look at how the Teal route and Pop 105 route interacted. However, we didn't get any interesting results this way
- In the future, we might want to look at more of the Appalcart routes. We would attempt to combine multiple routes and to see what changes when buses are added to the system.

## Thank You

Dr. Rahman Tashakkori, Dr. Vicky Klima, Nadine Lambert, NSF, the S-STEM Program, the McKinney Scholars Program, the Department of Computer Science, and the Department of Mathematics.
